Syringomyelia

Hydromyelia

cystic central canal dilatation

Syringomyelia

- cystic collection, or <u>syrinx</u>, that occurs within the <u>spinal</u> <u>cord</u> around the <u>central canal</u>, <u>not within</u>.
- Syringobulbia = brainstem syrinx extension
- Syringocephaly = brain/cerebral peduncle syrinx extension

Syringohydromyelia

features of both syringomyelia and hydromyelia

"Presyrinx state"

 reversible spinal cord edema produced by alterations in CSF flow dynamics

Syringomyelia

Syrinx

 is the collective name given to <u>hydromyelia</u>, <u>syringomyelia</u>, <u>syringobulbia</u>, <u>syringopontia</u>, <u>syringomesencephaly</u>, and <u>syringocephalus</u>.

Syringomyelia

 refers to a cystic collection, or <u>syrinx</u>, that occurs within the <u>spinal cord</u> around the <u>central canal</u>.

Syringomyelia

- Although syringomyelia is distinct from <u>hydromyelia</u>, in which there is simply dilatation of the central canal, it is very difficult to distinguish the two on imaging.
- Hence, the collective terms
 hydrosyringomyelia or
 syringohydromyelia can also be used to
 describe this fluid collection within the
 cord.

Pathology

- Hydrocephalus
- Chiari 1 or 2 malformation
- Myelomeningocele
- Other spinal dysraphism
- Tethered cord,
- Congenital scoliosis
- Spinal cord injury

DDX:

Ventriculus Terminalis

 Asymptomatic (normal) dilatation of terminal cord central canal only

Cystic Spinal Cord Tumor

 Cord expansion, cystic cavity surrounded by abnormal T2 signal, nodular enhancement

Myelomalacia

- Cord volume loss, gliosis
- No CSF signal cavitation on T1WI

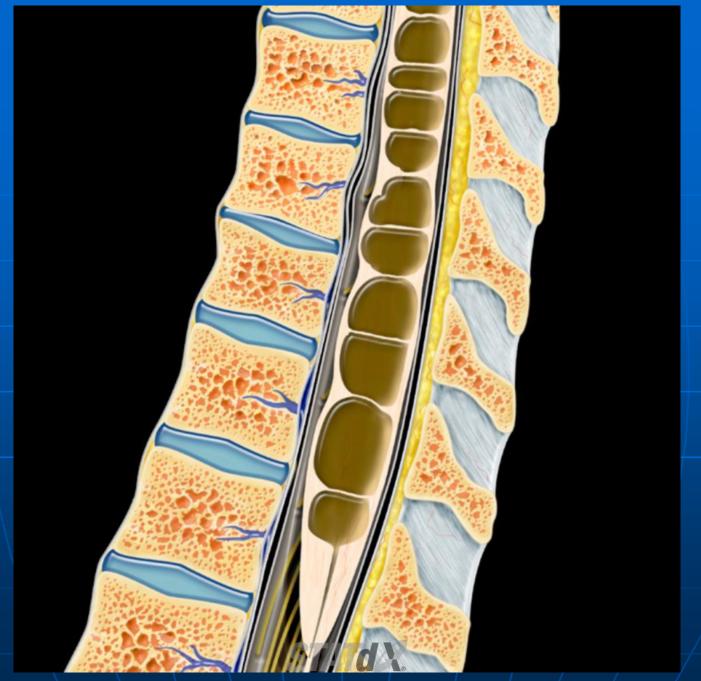

Checklist

Consider

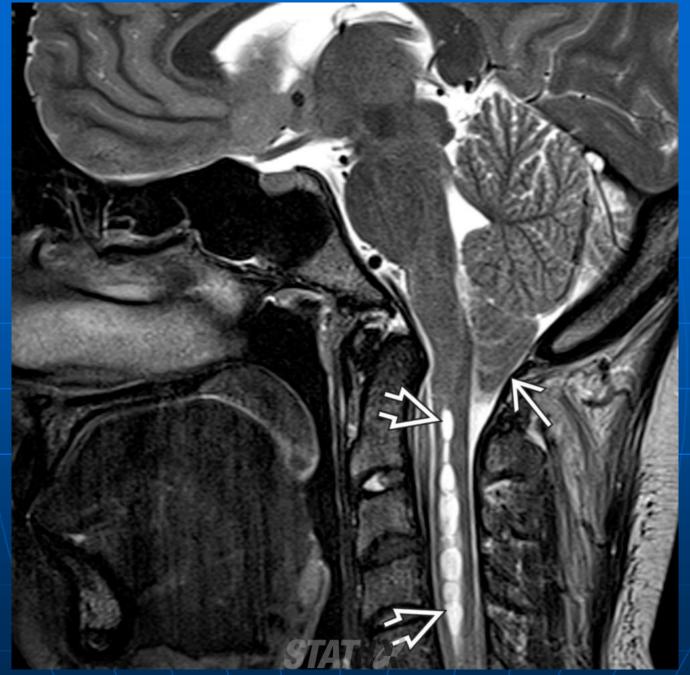

- Syrinx etiology influences treatment approach
- Despite septated appearance, large syrinx cavities usually contiguous

Image Interpretation Pearls

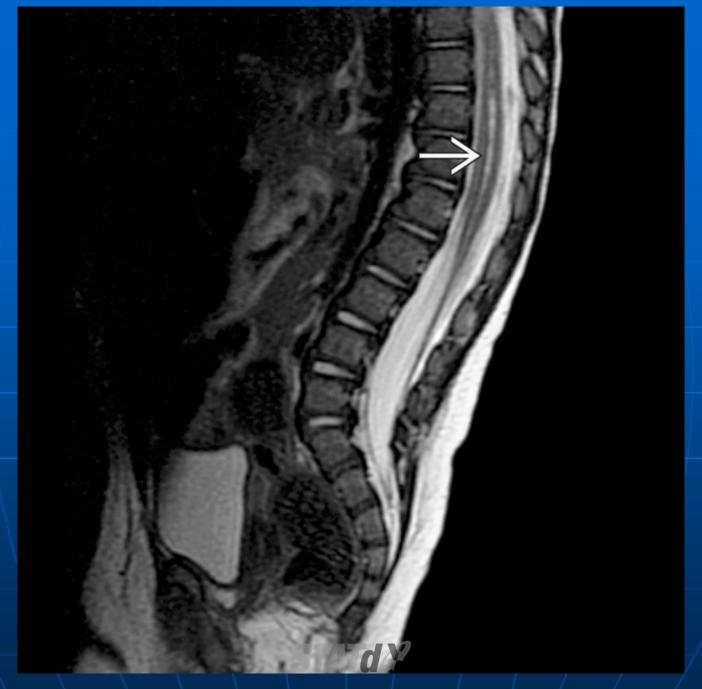

- Simple syringomyelia rarely enhances or produces diagnostic dilemma
- Contrast administration essential to exclude tumor in complicated cavitary lesions

Sagittal graphic demonstrates a large, sacculated, "beaded" spinal cord syrinx extending to the conus. Despite the loculated appearance of large syringes, the individual fluid spaces are contiguous and drainable using a single shunt catheter.

Sagittal T2WI FS MR (Chiari 1 malformation) shows inferior displacement of pointed ectopic cerebellar tonsils (white solid arrow) below the foramen magnum. Note associated cervical syringohydromyelia (white open arrow).

Sagittal T2WI MR shows low-lying spinal cord at L2/3 with terminal syringohydromyelia (white solid arrow).
